

# Operating Systems Hardening

Mamadu Bah, Lassine Guindo, Isaiah Stover

CTEC 450

# OS Hardening Steps

## 1. System Configuration

- Turn off unnecessary services to reduce security risks.
- Set up a firewall to block unauthorized access.
- Use strong passwords to protect user accounts.

## 2. User & Access Control

- Create user accounts with limited access to prevent misuse.
- Enable multi-factor authentication (MFA) for extra login security.
- Remove inactive accounts to reduce threats.

## 3. Patch & Update Management

- Install security updates to fix vulnerabilities.
- Enable automatic updates to stay protected.
- Remove old or unsupported software to prevent attacks.

## 4. Network Security

- Use firewalls & intrusion detection systems (IDS) to monitor traffic.
- Disable unused network services to reduce exposure.
- Use VPN encryption for secure remote access.

## 5. Logging & Monitoring

- Enable system logs to track activities.
- Use log analysis tools to detect threats.
- Set up alerts for unusual activity.

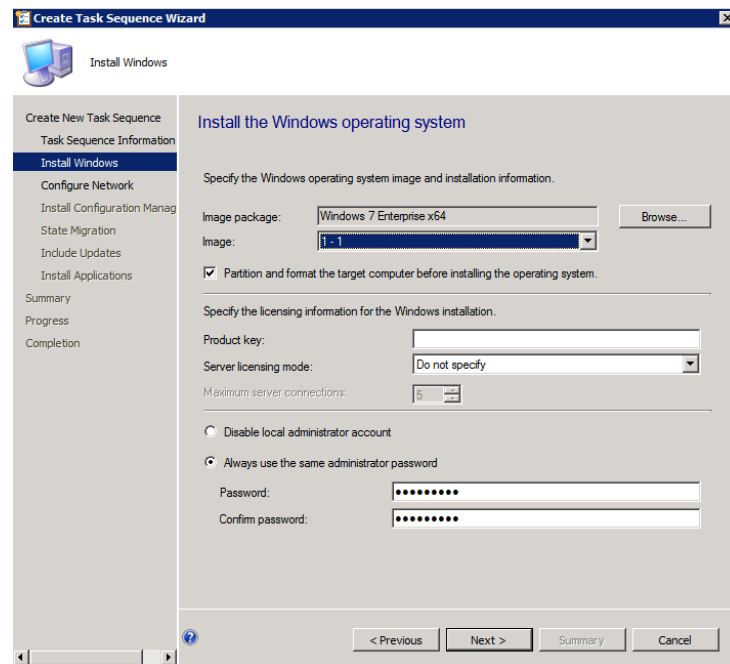

## 6. Application Security & Backup

- Allow only approved applications to run.
- Regularly update installed software to close security gaps.
- Create backups and store them securely to prevent data loss.

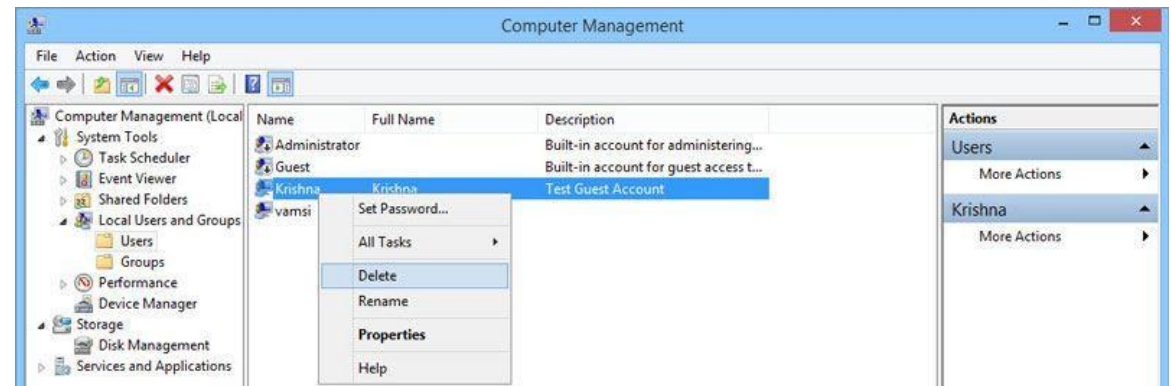

# Step-By-Step Guide

## Step 1: Configure the System

Open settings and disable unnecessary services.  
Set up a firewall to control network access. Enforce strong password policies in security settings.

- Step 2: Manage Users & Access
  - Create limited-access user accounts.
  - Enable multi-factor authentication (MFA).
  - Remove unused or inactive accounts.

# Step-By-Step Guide

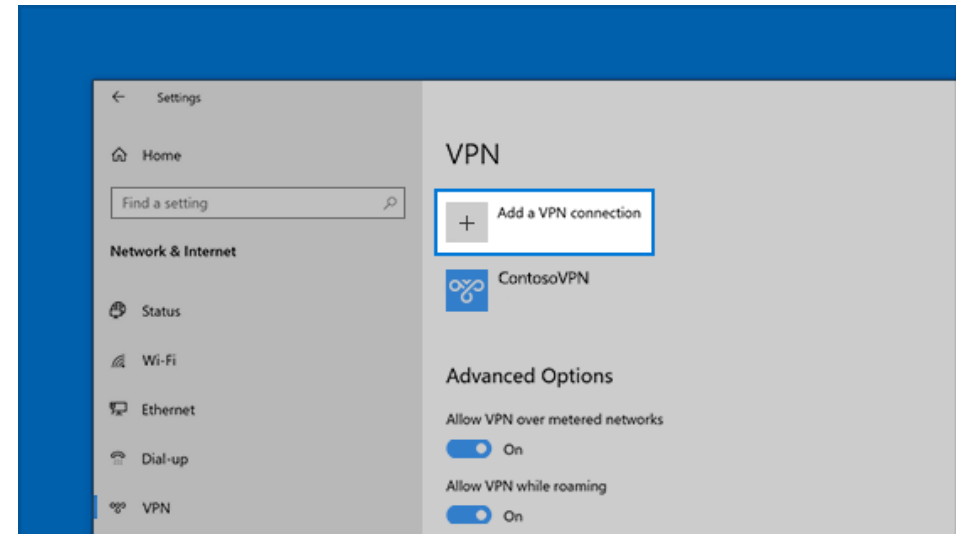

## Step 3: Apply Updates & Patches

- Check for pending OS and software updates.
- Enable automatic updates to prevent security gaps.
- Remove outdated applications.

## Step 4: Secure the Network

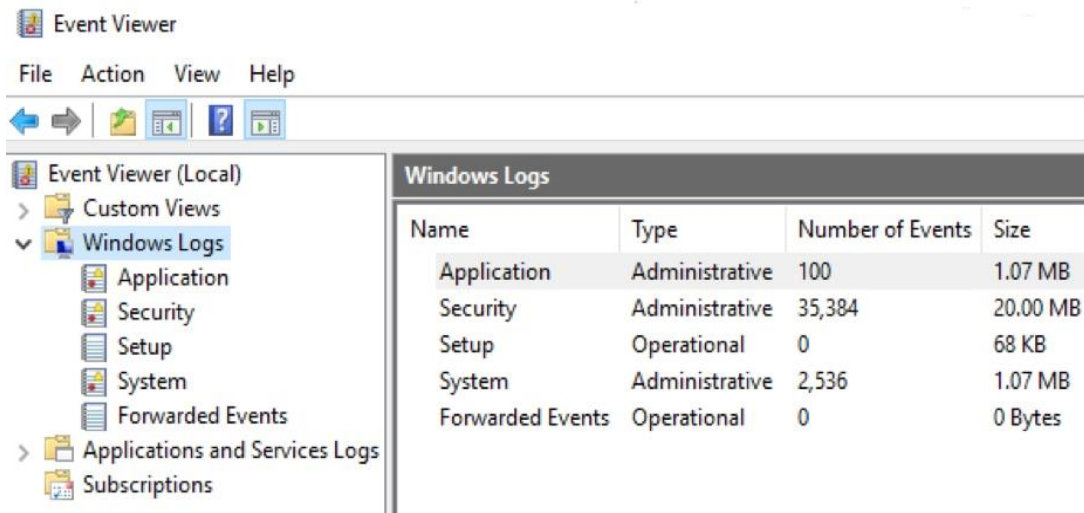

- Configure firewalls and set strict rules.
- Disable unused network ports & services.
- Use VPN for encrypted remote access.

# Step-By-Step Guide

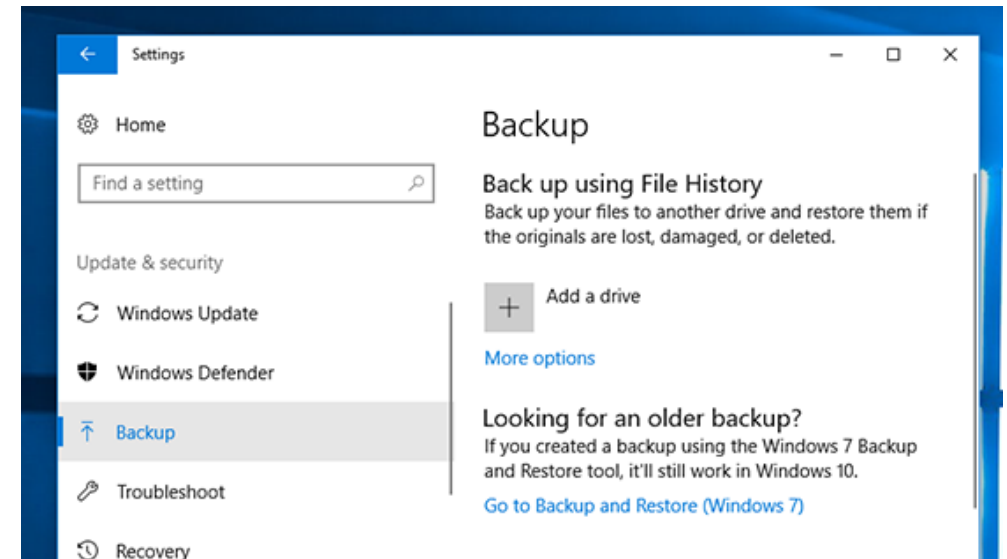

## Step 5: Enable Logging & Monitoring

- Turn on logging to track system activity.
- Set up alerts for failed login attempts.
- Regularly review logs for suspicious behavior.

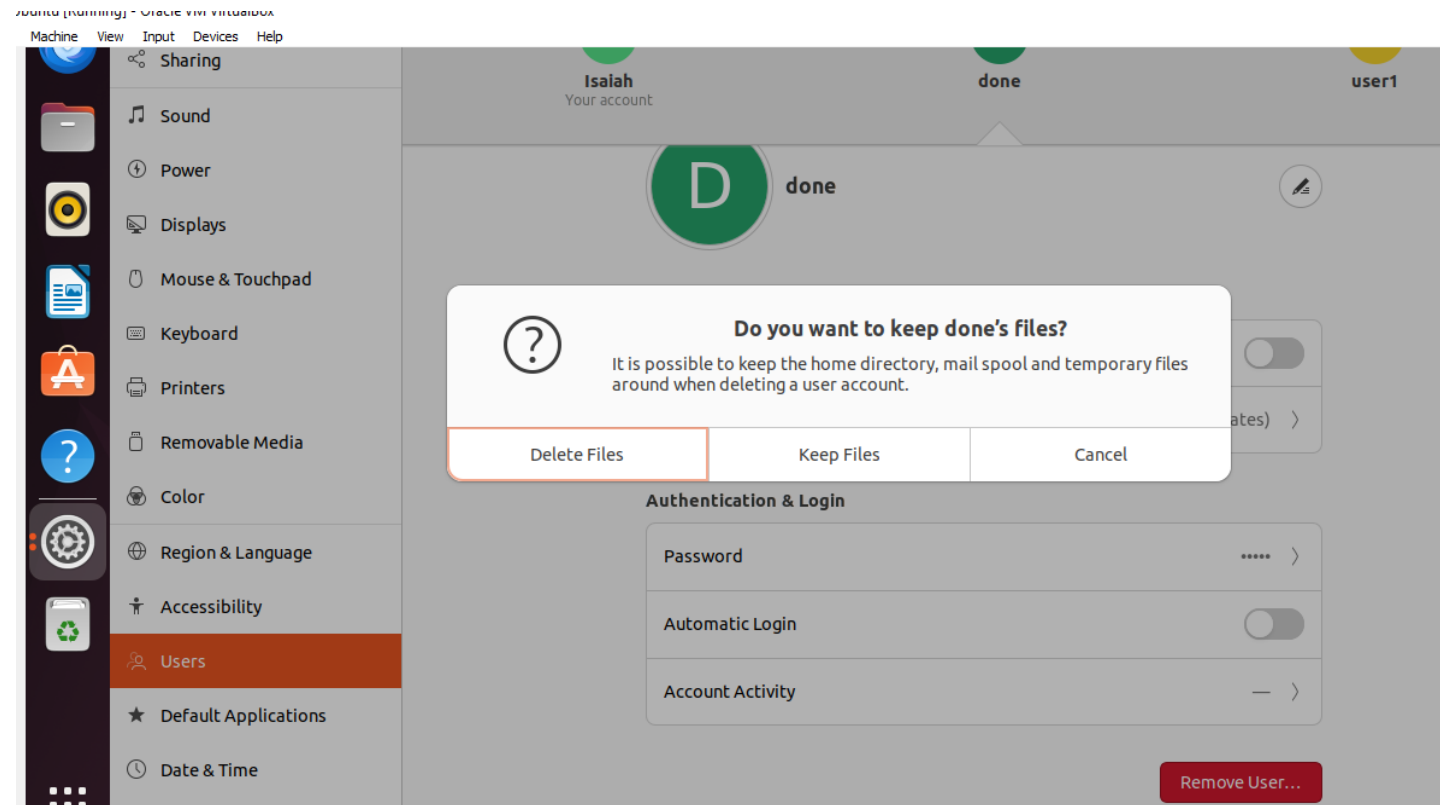

## Step 6: Secure Applications & Data

- Uninstall unnecessary software.
- Enable application whitelisting to block unknown apps.
- Back up important files and test restoration.

# System Configuration

# User access & Control

Create user accounts with limited access:

- I created new users with `sudo adduser [username]`.
- I used `sudo usermod -aG [group] [username]` to add users to appropriate groups, ensuring they only had access to necessary resources.

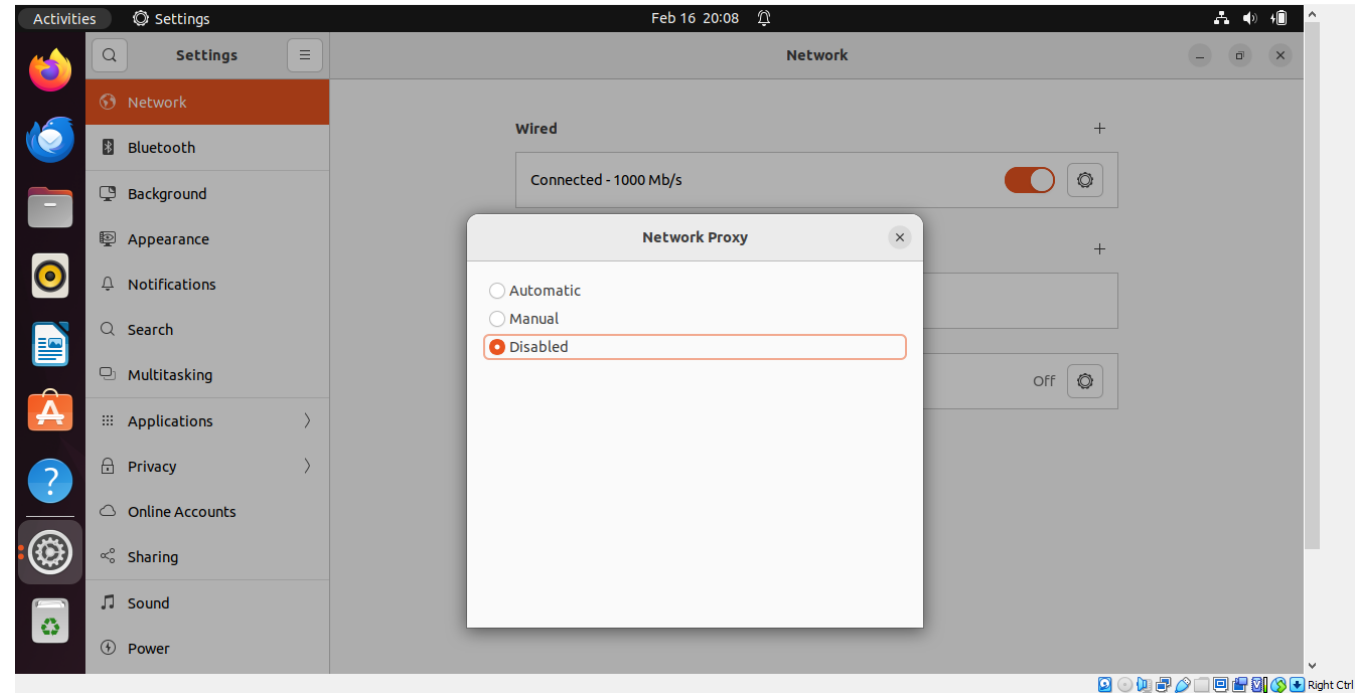

Remove inactive accounts:

- I used `lastlog` to see when users last logged in.
- For inactive accounts, I used `sudo userdel [username]` to remove them, reducing potential security threats.

# Network Security

## Disable unused network services:

- I navigated to the system's service management interface through the GUI.
- I reviewed the list of running services and disabled any unused network services by unchecking or stopping them

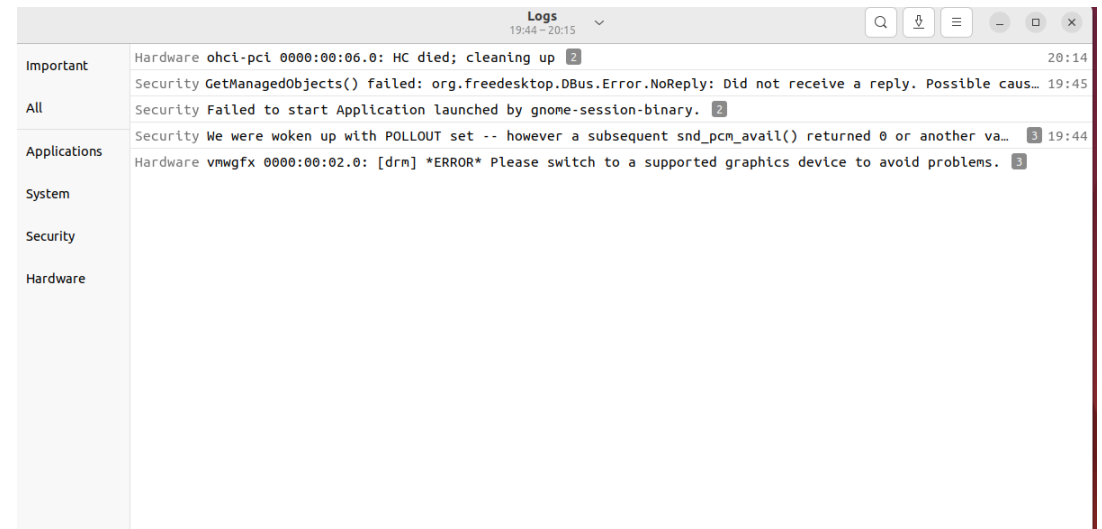

# Logging & Monitoring:

## Enable system logs:

- I accessed the system's logging settings through the GUI and ensured that logging was enabled and logs were being written to the appropriate files.
- I used the system's log viewer to confirm that activities were being tracked

# Application Security & Backup

Regularly update installed software:

I used the system's software update tool through the GUI to check for and install updates, ensuring all software was up to date and security gaps were closed.

I configured automatic updates through the system settings to ensure future updates were installed without manual intervention

```

```

# Assessment and Testing:

## Manual Vulnerability Assessment:

1. I manually reviewed the list of installed software and services to identify any outdated or vulnerable components.
2. I checked each service to ensure only necessary ones were running, and I disabled any that were not needed.
3. I reviewed the system's configuration files to check for any misconfigurations or non-compliant settings.

# Findings and Observations:

## Vulnerability Assessment Results:

- I found that all software was up to date, and no outdated components were present.
- I confirmed that all unnecessary services were disabled, reducing the attack surface

## Log Review Results:

- No suspicious activities were detected in the logs.
- All alerts were functioning as expected, with no unusual activities missed.

# Documentation and Finalization

## Organizing Content:

- I organized the guide into clear sections: Introduction, System Configuration, User & Access Control, Patch & Update Management, Network Security, Logging & Monitoring, Application Security & Backup, Assessment and Testing, and Conclusion
- I took screenshots at key points to visually guide the user through the process, ensuring that each screenshot was labeled.

# Conclusion

Hardening an operating system improves security by disabling unnecessary services, using firewalls, strong passwords, and multi-factor authentication, and regularly applying updates. Monitoring through logs and alerts, along with regular assessments, helps identify vulnerabilities. Consistent documentation of practices ensures ongoing protection against threats.
